INTRODUCTION

The Figitidae constitute a diverse family of cynipoid parasites comprising the subfamilies Parnipinae, Anacharitinae, Thrasorinae, Charipinae, and Figitidae ‘sensu stricto’ (Ronquist 1995, 1999; Ronquist & Nieves-Aldrey, 2001). The last taxon includes the Figitinae, Aspicerinae, Eucoilinae, Pycnostigminae and Emargininae (Ronquist 1994b, 1999).

The genus discussed in this paper, Acanthaegilips, is one of seven genera in the Anacharitinae (Ronquist 1999). It is easily separated from other anacharitines by the long and slender scutellar spine and some other unique features. Its distribution is entirely restricted to South and Central America, with the northernmost records reported here being from Mexico.

Figitidae are parasitoids of larvae of several insects. The recorded hosts of Anacharitinae are aphid-feeding neuropteran larvae belonging to the families Hemerobiidae and Chrysopidae (Weld 1952; Ronquist 1994a, 1995, 1999). However, hosts are unknown for many genera, including Acanthaegilips.

The genus Acanthaegilips was established by Ashmead (1897) on the basis of a single female col-
lected in Brazil. Weld (1921) added data to the original description based on the study of the female type specimen, and Díaz (1983) recorded the genus in Argentina, describing the male for the first time. The genus was recently redescribed by Ros-Farré et al. (2000).

Because of its different characters, Kovalev (1996) recently separated the genus from other anacharitines and placed it in a separate monotypic family. However, phylogenetic analysis indicates that the genus belongs to a monophyletic group comprising three neotropical Anacharitinae genera: Acanthaegilips, Solenofigites and Calofigites (Ros-Farré et al., 2000). This clade is deeply nested within the Anacharitinae. Thus, the genus cannot be maintained as a separate family (Ros-Farré et al., 2000).

Here, we describe 11 new species of Acanthaegilips. We show that the male specimens referred to A. brasiliensis by Díaz (1983) belong to a new species, which is described as A. diazi.

Despite the widespread use of new collecting techniques, such as Malaise, Moericke, and Noyes traps, the available material of several anacharitine genera is still relatively scanty. For this work we studied 56 specimens deposited in several collections that have accumulated specimens throughout many years of collecting efforts.

**MATERIAL AND METHODS**

We have studied material from the following institutions (curator in brackets):

- CNC – Canadian National Collections of Insects, Arachnids and Nematodes, Otawa, Ontario, Canada (J.D. Read)
- DCBU – Departamento de Biologia da Universidade Federal de São Carlos, SP, Brazil (A. Penteado-Dias)
- MLP – Museo de la Plata. República Argentina (N.B. Díaz)
- MACN – Museo Argentino de Ciencias Naturales (A. Roig)
- MZLU-MS – Museum of Zoology Lund University, Lund, Sweden – Coll. M. Sporrong
- MZUSP – Museu de Zoologia da Universidade de São Paulo, São Paulo, SP, Brazil (C.R.F. Brandão)
- UB – Universitat de Barcelona, Facultat de Biologia, Barcelona, Spain – Coll. P. Ros-Farré
- UCR – Universidad De Costa Rica (C. Godoy)
- USNM – United States National Museum of Natural History, Smithsonian Institution, Washington, DC, USA (D. Furth)
- MEAN – Museo Entomológico Asociación Nicaraguense de Entomología, Leon Nicaragua (J.M. Maes)

All holotypes were examined with SEM, without any previous coating and under very low voltage so as not to put the specimens under any risk. All other specimens, mounted on cardboard, were studied using stereomicroscopy and the drawings were obtained using camera-lucida.

The following special terms and measurements are employed in the descriptions:

- Transfacial line – shortest distance between the compound eyes.
- Postocular furrow – this furrow runs posterior to the compound eye. Ventrally, it joins the malar furrow close to the ventral margin of the eye.
- Malar furrow – this is a linear structure between the eye and the base of the mandible. It is usually formed like a noticeable furrow but sometimes it is a very weak sulcus. Nevertheless, the term malar furrow is used consistently here, in accordance with Ros-Farré et al. (2000).
- Notauli – in Acanthaegilips, the notauli are made up of a more or less distinct row of cells that also form part of the areolate sculpture covering the rest of the mesoscutum. Thus, the notauli are usually not well differentiated. A. alienus is an exception to this rule.
- Foveal carina – carina running from the anterior margin of the scutellar fovea posteriorly, sometimes reaching the posterior margin of the fovea.
- Median scutellar carina – carina running along the midline of the scutellum, anteriorly separating the scutellar foveae.

Remaining terms for skeletal structures and abbreviations follow Richards (1977), and Ronquist (1995). A description of the genus is not included in this study since a comprehensive description of the genus was provided by Ros-Farré et al. (2000).
Key to the identification of Acanthaegilips species:

1. Scutellum concave in dorsal view, roof-shaped, strongly inclined on each side of the median scutellar carina. Male flagellomeres never modified. Propodeum with three longitudinal ridges and without any sculpture between them. Notauli not made up of a row of cells of the areolate sculpture (only male known) .................

2. Marginal cell open; marginal vein always lacking (Figs. 5A, C), sometimes there is a very conspicuous line of hairs that looks like a vein, and the cell then appears to be closed .................. 

3. Malar furrow strongly curved. Postocular furrows present (Figs. 4A, B, E, F), if these furrow are weakly impressed then there is a line of hairs below them. Scutellar spine narrowing abruptly before apex (Figs. 2A, C, F, G) or end of scutellar disc narrowing abruptly and scutellar spine slender all the way (Fig. 2B) .........................

4. Scutellar foveae with an internal longitudinal carina (foveal carina), dividing them into two areas each (Figs. 2A, C). Pronotal plate produced, in lateral view, into a sharp and strongly raised dorsal tooth (Figs. 4A, C, F). Petiole as wide as long, sometimes slightly wider than long. Scutellar spine narrowing abruptly before apex (Figs. 2A, C, G) .........................

5. Foveal carina absent (Figs. 2B, 2F). Pronotal plate dorsally with a very small tooth (Figs. 4B, E). Petiole 1.5 to 2.0 times wider than long. Scutellar spine narrowed abruptly before apex or slender in all its length .............................

6. Pronotum in lateral view with areolate sculpture. Lateral pit of fovea present (Fig. 2C) (only female known) ............................................................

7. Scutellar disc narrows abruptly posteriorly and the scutellar spine is slender all the way (Fig. 2B); scutellar spine straight in lateral view (Fig. 4B). Lateral pit of scutellar fovea deep (Fig. 2B) ..........

8. Sculpture over scutum from the pronotum to the median sulcus as a carina (Fig. 3D), more evident when viewed in profile. Scutum in profile with a distinct hump. Pronotal plate, viewed laterally, with a pointed dorsal tooth (Fig. 3D) .............

9. Pronotal plate ending dorsally in a small tooth (Fig. 3C). Petiole laterally costate (only female known) ... A. masneri Sparrong & Ros-Farré n.sp. Pronotal plate rounded dorsally (Figs. 3A, E, F). Petiole laterally entirely smooth or slightly carinate anteriorly ........................................

10. Scutellar foveae smooth in the anterior part and reticulate posteriorly, more clearly on females (Fig. 1A). Male placoidal sensilla present and abundant from F1 to the end of the antenna .......
Scutellar foveae smooth (Figs. 1E, F). Male placodeal sensilla absent dorsally on F1 and scarce or absent dorsally on some of the following flagellomeres ...................................................... 11

11. Notauli complete, mesoscutum with weak areolate sculpture and between parapsidalsigna and parascutal impression without sculpture, parapsidalsigna strongly raised and conspicuous (Fig. 1F). Male placodeal sensilla present on F1 but dorsally absent from F1 to F5 and dorsally sparse from F6 to F7 (only male known) .............................................................. A. diazi Ros-Farré & Pujade-Villar sp. n.

Notauli incomplete reaching 1/2 the length of mesoscutum, mesoscutum coarsely areolate, parapsidalsigna quite conspicuous and not raised (Fig. 1E). Male placodeal sensilla absent dorsally on F1 and F2, on F3 and sometimes also on F4 very scarce .............................................................. A. ashmeadi Ros-Farré & Pujade-Villar sp. n.

FIGURE 1. Dorsal view of thorax of A. macropennis sp. n. (A), A. levis sp. n. (B), A. masneri sp. n. (C), A. brasilienisis (D), A. ashmeadi sp. n. (E), A. diazi sp. n. (F).
FIGURE 2. Dorsal view of thorax of *A. dentis* sp. n. (A), *A. huggerti* sp. n. (B), *A. occultus* sp. n. (C), *A. alienus* sp. n. (D), *A. exiguus* sp. n. (F), and *A. carinatus* sp. n. (G) and propodeum of *A. alienus* sp. n. (E).
Description of the new species of *Acanthaegilips* Ashmead, 1897

*Acanthaegilips alienus* Ros-Farré & Pujade-Villar sp. n.

(Figs. 2D, 2E, 4D)

**Studied material** – 1 ♂; ♀ unknown. Holotype: 1 ♂ (MZLU-MS) 22-VII-1990 at Prov. Pedernales, Sra. Bahoruco (1350 m), República Dominicana, L. Masner col.

Etymology – This name was chosen because this species is very different from all other *Acanthaegilips* species.

Colour – Head, mesosoma and petiole black, metasoma dark reddish brown. Scape yellowish brown, pedicel and flagellomeres brown. Legs yellowish brown except the apical part of hind tibia and metatarsus, which are brown. Mandibles light brown with dark brown teeth. Veins of wings medium brown.

**FIGURE 3.** Lateral view of *A. macropennis* sp. n. (A), *A. levis* sp. n. (B), *A. masneri* sp. n. (C), *A. brasiliensis* (D), *A. ashmeadi* sp. n. (E) and *A. diazi* sp. n. (F).
**Head**—Without pubescence. Malar furrow in upper part very curved. Postocular furrow present. Occipital carina strong (Fig. 4D). Malar space 0.62 times the height of the compound eye. Transfacial line 0.54 times the greatest width of head and 1.31 times the height of a compound eye. Pleurostomal lines weak. Antennal foramina separated from each other by 1.43 times the distance between the foramen and the compound eye.

**Antennae**—F1 to F4 cylindrical with a very small expansion at the apex, following flagellomeres cylindrical. Length of F1 1.2 the length of F2. Antennae without pubescence. Antennal formula: 10 (4.5); 3 (3.8); 11.5 (2.9); 9.5 (3.0); 10 (3.0); 10 (3.0); 10 (3.0); 10 (3.0); 10 (3.0); 10 (3.0); 10 (3.0); 9 (3.0); 9 (3.0); 12.5 (3.0). Placodeal sensilla start on F1. There are no modified flagellomeres.

**Mesosoma**—Anterior pronotal plate without pubescence. In dorsal part transversely carinulate changing to granulate laterally in level with the submedian depressions. Lateral pronotal carinae projecting dorsomedially to

---

**FIGURE 4.** Lateral view of *A. dentis* sp. n. (A), *A. buggetti* sp. n. (B), *A. occultus* sp. n. (C), *A. alienus* sp. n. (D) *A. exigus* sp. n. (E) and *A. carinatus* sp. n. (F).
form a small tooth (Fig. 4D). Lateral surface of pronotum with scattered hairs and with coarse areolate sculpture. Mesoscutum in lateral view 1.55 times higher than long; in dorsal view 1.37 times wider than long. Median mesoscutal impression weak, slightly longer than broad, notauli strongly and clearly impressed reaching 2/3 the length of mesoscutum, they are crossed by transverse carinae, they are not made up of a sequence of cells of the areolate sculpture (Fig. 2D). Line of hairs on the anterior and lateral margins of the scutum absent. Scutellum in dorsal view with the same length as the mesoscutum. Dorsal, posterolateral and posterior surfaces of scutellum smooth. Scutellum concave roof-shaped, median scutellar carina almost obsolete, only visible as a carina near the anterior margin. Lateral pit of scutellar fovea elongated and narrow, 2.7 times longer than wide; the distance from median scutellar carina to the inner margin of the pit 7.7 times the width of the pit. Scutellar disc in lateral view slopping to base of scutellar spine. End of scutellar disc narrowing abruptly to base of scutellar spine, which is slender, all the way (Fig. 4D) and straight (Fig. 2D). Mesopleural impression wide, straight and with transverse carinae. Mesopleural triangle with scattered hairs (Fig. 4D). Propodeum smooth between lateral and median propodeal carinae (Fig. 2E) and areolate in lateral areas.

Wings – Marginal cell open 2.73 times longer than wide. R1 absent. Marginal pubescence of the wing starting from the apical 3/4 of marginal cell but it is very sparse to the end of the cell.

Metasoma – Petiole 1.8 times as long as wide. Petiole with two dorsolateral furrows and ventrally with one longitudinal carina; weakly carinate laterally near anterior and posterior margins. Third abdominal tergum dorsally 0.81 the length of the fourth tergum.

Acanthaegilips ashmeadi Ros-Farré & Pujade-Villar sp. n.

(Figs. 1E, 3E)

Etymology – This name was chosen to honour Mr. William Harris Ashmead (1855-1908), U.S.A, who established the genus Acanthaegilips.

Length of head + mesosoma + metasoma in female: 2.75 mm; in male: 3.1 mm to 3.9 mm.

Colour – Female. Head, thorax and gaster black. Legs yellowish brown except hind coxa, which is black, and hind femur, tibia and tarsus, which are dark brown. Antennae dark brown, F7 to F10 ventrally lighter. Mandibles yellowish brown with darker teeth. Male. Differs from female in having the antennae entirely black. Veins of wings dark brown.

Head – Female. Head with scattered short hairs. Malar furrow slightly curved. Postocular furrow absent. Occipital carina absent. Malar space 0.58 to 0.71 times the height of the compound eye. Transfacial line 0.53 to 0.55 times the greatest width of head and 1.03 to 1.08 times the height of a compound eye. Antennal
foramina separated from each other by the same distance as that between the foramen and the compound eye. Pleurostomal lines weak. Male. Malar space 0.50 to 0.63 times the height of the compound eye. Transfacial line 0.52 to 0.57 times the greatest width of head and 1.03 to 1.10 times the height of a compound eye.

Antennae – Female. F1 to F3 cylindrical with a very small expansion at the apex. Following flagellomeres cylindrical. Length of F1 1.4 to 1.5 the length of F2. Scape and pedicel with sparse pubescence. The pubescence on the flagellomeres getting shorter and denser towards the 4 or 5 last flagellomeres, which have dense but very short pubescence. Antennal formula: 10 (3.5): 3 (2); 15 (2); 10 (2); 9 (2); 6.5 (2); 6 (2); 5 (3); 5 (3); 4 (2); 8 (2). Placodeal sensilla start on F2 but they are absent on the dorsal part of this segment and very scarce on dorsal part of F3. Male. Length of F1 1.36 to 1.44 times the length of F2. Flagellomeres covered with very short pubescence. Placodeal sensilla start on F1 but they are absent in the dorsal part of F1 and F2, on F3 and sometimes also on F4 they are very scarce at the dorsal part. F3 to F5 slightly expanded dorsolaterally with a longitudinal ridge on the raised part. Antennal formula: 13 (5.8): 4.5 (5.0); 25 (5.0); 18 (4.9); 17 (4.9); 17 (4.8); 15 (4.7); 12.5 (4.7); 12 (4.8); 11.5 (4.8); 11.5 (4.8); 11 (4.7): 13.5 (4.5).

Mesosoma – Female. Anterior pronotal plate rounded dorsally (Fig. 3E) and with a few white hairs near lateral and dorsolateral margins; near the dorsal margin there is a weak trace of transversely carinulate sculpture. Lateral surface of pronotum with sparse pubescence and with coarse areolate sculpture. Mesoscutum in lateral view 1.70 to 1.80 times higher than long; in dorsal view 1.30 to 1.42 times wider than long. Median mesoscutal impression short, not much longer than wide. Notauli reaching 1/2 the length of mesoscutum (Fig. 1E). There is a conspicuous line of hairs on the anterior and lateral margins of the mesoscutum. Scutellum in lateral view 1.70 to 1.80 times higher than long; in dorsal view 1.30 to 1.42 times wider than long. Median mesoscutal impression short, not much longer than wide. Notauli reaching 1/2 the length of mesoscutum (Fig. 1E). Antennal formula: 10 (3.5): 3 (2); 15 (2); 10 (2); 9 (2); 6.5 (2); 6 (2); 5 (3); 5 (3); 4 (2); 8 (2). Placodeal sensilla start on F2 but they are absent on the dorsal part of this segment and very scarce on dorsal part of F3. Male. Length of F1 1.36 to 1.44 times the length of F2. Flagellomeres covered with very short pubescence. Placodeal sensilla start on F1 but they are absent in the dorsal part of F1 and F2, on F3 and sometimes also on F4 they are very scarce at the dorsal part. F3 to F5 slightly expanded dorsolaterally with a longitudinal ridge on the raised part. Antennal formula: 13 (5.8): 4.5 (5.0); 25 (5.0); 18 (4.9); 17 (4.9); 17 (4.8); 15 (4.7); 12.5 (4.7); 12 (4.8); 11.5 (4.8); 11.5 (4.8); 11 (4.7): 13.5 (4.5).

Wings – Female. Marginal cell closed 3.13 to 3.20 times longer than wide. Marginal pubescence of the wing present starting from vein R1. Male. Marginal cell 2.9 to 3.0 times longer than wide.

Metasoma – Petiole 3.0 to 3.3 times as long as wide. Petiole dorsally smooth; laterally smooth but near the anterior end there are a few short cariniae; ventrally costate. Third abdominal tergum dorsally 0.75 to 0.88 the length of the fourth tergum. Male. Petiole 3.2 to 3.3 times as long as broad. Third abdominal tergum dorsally 0.69 to 0.85 the length of the fourth tergum.

Acanthaegilips carinatus Ros-Farré & Pujade-Villar sp. n. 
(Figs. 2G, 4F)

Studied material – 1 ♂, 1 ♀. Holotype: 1 ♂ (DCBU) 31-VIII-98 346 p.m. São Carlos (Brasil) Carlos Henrique col. Paratype: 1 ♀ (MZUSP) same data of holotype.

Etymology – This name was chosen because of the coarse transverse cariniae of the pronotal sides.

Length of head + mesosoma + metasoma in female: 2.33 mm; in male: 2.63 mm.

Head — Female. Head without pubescence, except for lines of hairs running with malar and postocular furrows. Malar furrow very weak, only marked by a change in the integument curvature; postocular furrow weak. Occipital carina strong. Malar space 0.63 times the height of the compound eye. Transfacial line 0.53 times the greatest width of the head and 1.07 times the height of a compound eye. Pleurostomal lines well impressed. Antennal foramina separated from each other by 2.25 times the distance between the foramen and the compound eye. Male. Malar furrow only marked by a change on the integument curvature but not as weak as in the female. Malar space 0.55 times the height of the compound eye. Transfacial line 0.52 times the greatest width of the head and with the same length as the height of a compound eye. Antennal foramina separated from each other by 2.16 times the distance between the foramen and the compound eye.

Mesosoma — Female. Lateral pronotal carinae projecting dorsomedially to form a very much raised tooth (Fig. 4F). Anterior pronotal plate with a few scattered hairs near dorsolateral margins and transversely carinate. Lateral surface of pronotum densely pubescent in ventral part with coarse transverse carinae, in dorsal part with areolate-rugose sculpture. Mesoscutum in lateral view 1.67 times higher than long; in dorsal view 1.25 times wider than long. Median mesoscutal impression short, longer than wide. Notauli complete (Fig 2G). Line of hairs on the anterior and lateral margins of the scutum absent. Scutellum in dorsal view 1.05 times the length of the mesoscutum. Scutellar foveae in anterior part with an internal short longitudinal carina, dividing the anterior area of each fovea into two areas, scutellar foveae mostly smooth with rugose sculpture near its posterior margin. Lateral pit of scutellar fovea absent. Scutellar spine broad, narrowing abruptly before apex (Fig 2G). Scutellar disc in lateral view steeply slopping to base of scutellar spine, which is upwards directed at base and curved downwards, the apex is ventrally directed. Mesopleural impression rather narrow strongly curved in the apical part and with a lot of transverse carinae (Fig. 4F). Mesopleural triangle with very sparse pubescence. Propodeum with areolate sculpture, lateral and median propodeal carinae present, these are flat and wide in upper part. Male. Mesoscutum in lateral view 1.55 times higher than long; in dorsal view 1.19 times wider than long. Scutellum in dorsal view with the same length as that of the mesoscutum. Scutellar foveae more sculptured posteriorly than in the female. Lateral pit of scutellar fovea obstructed. Scutellar spine very slightly curved. Mesopleural impression not as curved as in the female.

Wings — Female. Marginal cell open 2.88 times longer than wide. R1 practically absent. Marginal pubescence of the wing starting from the apical 1/2 of marginal cell but it is very sparse to the end of the cell. Male. Marginal cell 3.38 times longer than wide. Marginal pubescence starting from the basal 1/3.

Metasoma — Female. Petiole as long as wide. Petiole dorsally smooth, laterally and ventrally costate. Third abdominal tergum dorsally 0.5 times the length of the fourth tergum. Male. Petiole wider than long. Dorsally, laterally and ventrally costate.

Acanthaegilips dentis Ros-Farré & Pujade-Villar sp. n.
(Figs. 2A, 4A)

Studied material — 1 ♀; ♂ unknown. Holotype: 1 ♀ (UCR) 16-XI-1994 at Heredia, Est. Biol. La Selva. (100 m) (Costa Rica). 10°26'N/84°01'W Fot 38, P. Hanson col.

Etymology — This name was chosen because the tooth of the anterior pronotal plate, which is very much raised.

Length of head + mesosoma + metasoma: 2.55 mm.

with medium brown teeth. Antennae light brown with exception of the four last flagellomeres, which are dark brown. Legs light brown with the exception of the metatibia and the metatibia, which are dark brown. Veins of wing light brown.

**Head**—Without pubescence. Malar furrow very curved, postocular furrow well impressed (Fig. 4A). Occipital carina strong. Clypeal zone not marked and pleurostomal lines very weak. Malar space 0.65 times the height of the compound eye. Transfacial line 0.58 times the greatest width of the head and 1.11 times the height of a compound eye. Antennal foramina separated from each other by 1.5 times the distance between the foramen and the compound eye.

**Mesosoma**—Lateral pronotal carinae projecting dorsomedially to form a very much raised tooth (Fig. 4A). Anterior pronotal plate with short scattered hairs on the margins and with a very conspicuous rugulose sculpture. Lateral surface of pronotum with dense pubescence and with areolate sculpture. Mesoscutum in lateral view 1.66 times higher than long; in dorsal view 1.17 times wider than long. Median mesoscutal impression short, longer than broad. Notauli complete (Fig. 2A). Line of hairs on the anterior and lateral margins of the scutum absent. Scutellum in dorsal view 1.05 times the length of the mesoscutum. Scutellar foveae smooth and with an internal longitudinal carina dividing them into two areas each. There is rugose sculpture at the area compressed between the end of scutellar foveae and before the apex. Lateral pit of scutellar fovea almost circular, 1.1 times longer than wide; the distance from median scutellar carina to the inner margin of the pit 2.78 times the width of the pit. Scutellar spine broad narrows abruptly before apex (Fig. 2A). Scutellar disc in lateral view steeply slopping to base of scutellar spine, which is strongly directed upwards at base and curved downwards, so that the apex is ventrally directed. Mesopleural impression rather narrow curved in the apical part and with few coarse transverse carinae (Fig. 4A). Mesopleural triangle sparsely pubescent anteriorly and more sparsely pubescent posteriorly (Fig. 4A). Propodeum with areolate sculpture. Median and lateral propodeal carinae present.

**Wings**—Marginal cell open 2.6 times longer than wide. R1 short not reaching the margin of the wing. Marginal pubescence of the wing starting from the apical 1/3 of marginal cell but it is very sparse to the end of the cell.

**Metasoma**—Petiole 1.12 times as long as wide. Petiole dorsally, laterally and ventrally costate. Third abdominal tergum dorsally 0.63 the length of the fourth tergum.

**Acanthaegilips diazi** Ros-Farré & Pujade-Villar sp. n.
(Figs. 1F, 3F)

**Studied material**—3 ♂; ♀ unknown. Holotype: 1 ♂ (MLP) 16-11-81 at San Javier, San Miguel de Tucumán, Tucumán (República Argentina) S. Mulvany, N. Díaz, G. Armesto, P. Fidalgo col. Paratypes: 2 ♂, Same Holotype’s data.

**Etymology**—This name was chosen to honour Dra. Norma Beatriz Díaz, Argentina, who loaned us all type specimens of this species.

Length of head + mesosoma + metasoma: 2.9 mm to 3.4 mm.

**Colour**—Head black, mesosoma black with exception of the lateroventral margins of pronotum, the anterior and lateral margins of mesoscutum, the mesopleural triangle and the notauli, which sometimes are red or amber colour. Metasoma blackish brown. Pedicel reddish brown, scape and F1 to F5 or F6 black to blackish brown with reddish colour on the apex, following flagellomeres changing to light brown. Mandibles light brown with medium brown teeth. Legs yellow with exception of the last ones, which are dark to medium brown.

**Head**—Covered by quite dense long pubescence. Malar furrow slightly curved, in upper part strongly curved. Postocular furrow absent. Occipital carina present. Malar space 0.61 to 0.65 times the height of the compound eye. Transfacial line 0.51 to 0.52 times the greatest width of the head and 1.07 to 1.10 times the height of a com-
pound eye. Pleurostomal lines weak. Antennal foramina separated from each other by 1.20 to 1.25 times the distance between the foramen and the compound eye.

**Mesosoma** – Anterior pronotal plate rounded dorsally (Fig. 1F) with quite dense pubescence at the lateral areas and sparse pubescence in lateroanterior margins, near the dorsal margin weakly transversely carinulate. Lateral face of pronotum with dense long pubescence, the sculpture is between rugose and areolate. Mesoscutum in lateral view 1.69 to 2.03 times higher than long; in dorsal view 1.24 to 1.27 times wider than long. Median mesoscutal impression very short as long as broad. Notauli complete and well differentiated. The areolate sculpture of the mesoscutum is laterally effaced, in some specimens is weak in medial part (Figs. 1F, 3F). There is a very conspicuous line of hairs on the anterior and lateral margins of the mesoscutum. Scutellum in dorsal view 1.0 to 1.1 times the length of the mesoscutum. Scutellar fovea smooth (Fig. 1F) the lateral carinae of fovea are not straight in the posterior part. Lateral pit of scutellar fovea big, 1.5 to 2.0 times longer than wide; the distance from median scutellar carina to the inner margin of the pit 2.87 to 3.50 times the width of the pit. Scutellar spine broad at base narrowing gradually towards apex (Fig. 1F). Scutellar disc in lateral view slightly slopping to base of scutellar spine, which is horizontally directed at base and very slightly curved downwards towards apex (Fig. 3F). Mesopleural impression straight and wide (strongly wider on the basal part) and without transverse carinae. Parapsidalsigna strongly marked and continuous, sometimes meeting on the anterior part. Mesopleural triangle with dense pubescence anteriorly and sparse pubescence posteriorly. Propodeum with coarse, areolate sculpture, lateral and median propodeal carinae absent.

**Wings** – Marginal cell closed, 3.22 to 3.40 times longer than wide. Marginal pubescence of the wing starting from vein R1.

**Metasoma** – Petiole 2.0 to 2.2 times as long as wide, dorsally smooth, laterally smooth, dorsolaterally near the anterior end costate, ventrally longitudinally costate. Third abdominal tergum dorsally 1.00 to 1.08 the length of the fourth tergum.

**Acanthaegilips exiguus** Ros-Farré & Pujade-Villar sp. n. (Figs. 2F, 4E)

**Studied material** – 1♂; ♀ unknown. Holotype: 15♂ (USNM) XII-1967 at Kingston, Jamaica, NLH Krauss col.

**Etymology** – This name was chosen due to the small length of this species.

**Length of head + mesosoma + metasoma:** 2.29 mm.

**Colour** – Head black, metasoma medium to light reddish brown with exception of propodeum and apex of scutellar spine, which are dark brown. Metasoma blackish brown. Antennae light brown. Mandibles reddish brown with darker tooth. Legs brown with exception of the tibia and tarsus of the first and medium legs, which are light brown. Veins of wings medium brown.

**Head** – Covered with very short and scattered hairs. Malar furrow very curved and not much strongly impressed. Postocular furrow present and not much strongly impressed (Fig. 4E). There are some scattered hairs in the postocular furrow and in the upper part of malar furrow. Pleurostomal lines weak. Occipital carina absent. Malar space 0.47 times the height of the compound eye. Transfacial line 0.5 times the greatest width of the head and 1.0 times the height of a compound eye. Antennal foramina separated from each other by 2.61 times the distance between the foramen and the compound eye.

Mesosoma – Lateral pronotal carinae projected dorsomedially to form a small and few raised tooth (Fig. 4E). Pronotal plate with few scattered short hairs, and with coriaceous sculpture. Lateral surface of pronotum with quite dense pubescence, weak areolate-reticulate sculptured in the apical part and with irregular transverse carinae in the ventral part. Mesoscutum in lateral view 1.48 times higher than long; in dorsal view 1.22 times wider than long. Median mesoscutal impression very short and little longer than broad, notauli complete (Fig. 2F). Line of hairs on the anterior and lateral margins of the mesoscutum absent. Carinae between areolate sculpture wider and shinier than all other species of the group. Scutellum in dorsal view 0.91 times the length of the mesoscutum. Scutellar foveae smooth in the most part and with rugose sculpture in their posterior part (Fig. 2F). Lateral pit of fovea obstructed, superficial 1.6 times longer than wide; the distance from median scutellar carina to the inner margin of the pit 3.8 times the width of the pit. Scutellar disc in lateral view steeply slopping to base of scutellar spine, which is directed upwards at base and curved downwards, so that the apex is ventrally directed. Mesopleural impression narrow curved in upper part and with abundant weak transverse carinae. Mesopleural triangle glabrous. Propodeum with areolate sculpture. Median and lateral propodeal carinae present. The lateral carinae are wide and flat in upper part.

Wings – Marginal cell open 2.75 times longer than wide. R1 absent. Marginal pubescence of the wing starting from the apical 2/3 of marginal cell but it is very sparse to the end of the cell.

Metasoma – Petiole 1.8 times as long as wide, dorsally smooth, laterally and ventrally costate. Third abdominal tergum dorsally 0.6 times the length of the fourth tergum.

Acanthaegilips huggerti Sporrong & Ros-Farré sp. n.
(Figs. 2B, 4B)

Etymology – This name was chosen to honour Dr. Lars Huggert, Sweden, who has collected the type specimen.

Length of head + mesosoma + metasoma in female: 2.58 mm; in male: 2.63 mm.

Colour – Female. Head and mesosoma black, metasoma blackish brown. Antennae light or reddish brown. Mandibles light yellowish brown with reddish brown teeth. Legs light brown with exception of the basal 2/3 of the metacoxa, which is dark brown. Veins of wing yellowish brown. Male. Differs from female in having scape and pedicel light brown, flagellomeres medium to dark brown, lighter lateroventrally.

Head – Female. Head with scattered short hairs. Malar furrow in upper part very curved. Postocular furrow present. Occipital carina strong. Malar space 0.58 to 0.62 times the height of the compound eye. Transfacial line 0.53 to 0.56 times the greatest width of the head and 1.15 to 1.16 times the height of a compound eye. Pleurostomal lines very marked. Antennal foramina separated from each other by 1.17 to 1.20 times the distance between the foramen and the compound eye. Male. Malar space 0.6 to 0.7 times the height of the compound eye. Antennal foramina separated from each other by 1.25 to 1.29 times the distance between foramen and the compound eye.

Mesosoma – Female. Anterior pronotal plate almost glabrous with coriaceous sculpture. Lateral pronotal carinae projecting dorsomedially to form a blunt, little tooth (Fig. 4B). Lateral surface of pronotum with scattered
hairs and with coarse areolate sculpture. Mesoscutum in lateral view 1.6 times higher than long; in dorsal view 1.29 times wider than long. Median mesoscutal impression very short, at most little longer than broad. Notauli reaching 1/2 or 1/3 the length of mesoscutum (Fig. 2B). Line of hairs on the anterior and lateral margins of the mesoscutum absent. Scutellum in dorsal view of the same length as that of the mesoscutum. Scutellar foveae smooth with some weak sculpture at its posterior margin. Lateral pit of scutellar fovea rather small and almost circular, 1.2 times longer than wide; the distance from median scutellar carina to the inner margin of the pit 4.0 times the width of the pit. End of scutellar disc narrowing abruptly to base of scutellar spine, which is slender all the way (Fig. 2B). Scutellar disc in lateral view steeply sloping to base of scutellar spine. Scutellar spine straight not directed ventrally (Fig. 4B). Mesopleural impression rather narrow straight and with few transverse carinae. Mesopleural triangle glabrous. Propodeum areolate but not coarsely, median and lateral propodeal carinae present. Male. Mesoscutum in lateral view 1.60 to 1.67 times higher than long; in dorsal view 1.15 to 1.33 times wider than long. Scutellum in dorsal view of the same length as that of the mesoscutum. Lateral pit of scutellar fovea 1.20 to 1.33 times longer than wide; the distance from median scutellar carina to the inner margin of the pit 3.33 times the width of the pit. Mesopleural impression with only one or two weak transverse carinae.

Wings – Female. Marginal cell open; between 2.70 and 2.80 times longer than wide. R1 practically non-existent. Marginal pubescence of the wing starting from vein R1. Margin of the marginal cell sparsely pubescent anteriorly and densely pubescent apically. Male. Marginal cell 3.14 to 3.44 times longer than wide; its margin rather densely pubescent anteriorly and apically.

Metasoma – Female. Petiole between 1.7 and 2.0 times as long as wide. Petiole dorsally smooth laterally and ventrally longitudinally costate. Third abdominal tergum dorsally between 0.60 and 0.71 the length of the fourth tergum.

Acanthaegilips levis Ros-Farré & Pujade-Villar, sp. n.
(Figs. 1B, 3B)

Studied material – 2 ♀; ♂ unknown. Holotype: 1 ♀ (UCR) III-1995 at San José, Zurqui de Moravia (1600 m), (Costa Rica), Hanson & Godoy col. Paratype: Costa Rica: 1 ♀ (UCR), X/XII-1990 and same Holotype’s data.

Etymology – This name was chosen because the scutellum in dorsal view is very smooth, flat and shining and the lateral carinae of scutellar foveae are weakly impressed.

Length of head + mesosoma + metasoma: 2.9 mm to 3.1 mm.

Colour – Although we only examined two specimens they had different colour. Head black, mesosoma and metasoma black or dark brown. Antennae medium brown or black with amber colour towards apex from F1 to F5. Mandibles medium or light brown with reddish brown teeth. Legs medium to dark brown with exception of procoxa and mesocoxa, which are light brown. Veins of wing medium brown.

Head – Covered with very few scattered quite long hairs. Malar furrow slightly curved; postocular furrow absent (Fig. 3B). Occipital carinae weak. Pleurostomal lines well impressed and wide. Malar space 0.61 to 0.63 times the height of the compound eye. Transfacial line 0.57 times the greatest width of the head and 1.21 times the height of a compound eye. Antennal foramina separated from each other by 1.00 to 1.14 times the distance between the foramen and the compound eye.

Antennae – F2 to F4 weakly expanded in width at the apex, following flagellomeres cylindrical. Length of F1 1.5 the length of F2. Scape and pedicel covered with very sparse pubescence. First flagellomeres covered with sparse pubescence this is getting dense towards last flagellomeres. Antennal formula: 12 (3): 3 (2): 14 (2): 9 (2): 8 (2): 7 (2): 6 (2): 5.5 (2): 5 (3): 5 (3): 4.5 (3.5): 11 (3). Placodeal sensilla start on F1 but they are ventrally absent at the basal 1/2 and scarce at the upper 1/2 of F1 and absent on the dorsal part of F1 and F2 and scarce on the dorsal part of F3.

Mesosoma – Anterior pronotal plate very raised dorsomedially but rounded not forming a tooth (Fig. 3B) and with sparse pubescence on the lateral margins, in dorsal part weakly transversely carinate and changing to coriaceous in level with the submedian depressions. Lateral surface of pronotum covered with sparse pubescence and with coarse areolate sculpture. Mesoscutum in lateral view 1.45 times higher than long; in dorsal view 1.25 times wider than long. Median
mesoscutal impression very short a little longer than broad. Notauli reaching 1/2 to 2/3 the length of mesoscutum (Fig 1B). There is a weak line of hairs on the anterior and lateral margins of the mesoscutum. Scutellum in dorsal view 1.31 times the length of the mesoscutum. Scutellar foveae nude (Fig 1B). Scutellar spine dorsally very smooth, lateral ridges of the foveae not much marked, and narrowing gradually. Lateral pit of scutellar fovea rather big and oval, 1.45 to 1.50 times longer than wide; the distance from median scutellar carina to the inner margin of the pit 3.60 to 3.90 times the width of the pit. Scutellar spine broad at base and narrowing gradually towards apex (Fig 1B). Scutellar disc in lateral view slopping to base of scutellar spine, which is slightly upwards directed and almost horizontally directed towards apex but the apex not ventrally directed (Fig 3B). Mesopleural impression wide and straight with 3 or 4 very effaced transverse carinae (Fig. 3B). Mesopleural triangle with sparse pubescence anteriorly and with some scattered hairs posteriorly. Propodeum with coarse areolate sculpture, lateral and median propodeal carinae absent.

Wings – Marginal cell open 3.37 to 3.50 times longer than wide. R1 arriving near the margin but not reaching it as in the Fig. 3A. Marginal pubescence starting from vein R1.

Metasoma – Petiole 2.6 times as long as wide, smooth dorsally, laterally and ventrally costate. Third abdominal tergum dorsally 0.68 times the length of the fourth tergum.

**Acanthaegilips macropennis** Sporrong & Ros-Farré. sp. n.
(Figs. 1A, 3A)

**Studied material** – 10 ♂ & 4 ♀. Holotype: 1 ♀ (in CNC) 17-II-1983 at Napo bellow Papallacta 3000 m, (Ecuador), L.M. Masner col. Paratypes: Ecuador: 4 ♂ & 1 ♀ same Holotype’s data. 6 ♂ & 2 ♀ (in MZLU-MS) 24-II-83 at Napo Papallacta 3800 m., Lars Huggert col.

**Etymology** – This name was chosen because the large wings, which this species has in common with several species of Eucoilinae collected at the same altitudes.

Length of head + mesosoma + metasoma in female: 3.5 mm to 4.4 mm; in male: 3.2 mm to 3.9 mm.

**Colour** – Female. Head and mesosoma black, metasoma blackish brown. Scape, pedicel, F1 and F2 black, remaining flagellomeres changing to brown. Mandibles brown with reddish brown teeth. Legs dark brown. Veins of wing medium to dark brown. Male. Differs from female in having all of the flagellomeres black.

**Head** – Female. Covered by sparse long hairs. Malar furrow slightly curved; postocular furrow absent (Fig. 3A). Occipital carina absent. Malar space 0.77 to 0.92 times the height of the compound eye. Transfacial line 0.56 to 0.58 times the greatest width of the head and 1.15 to 1.43 times the height of a compound eye. Pleurostomal lines very weak. Antennal foramina separated from each other by 0.76 to 0.80 times the distance between the foramen and the compound eye. Male. Malar space 0.66 to 0.77 times the height of the compound eye. Transfacial line 0.54 to 0.57 times the greatest width of the head and 1.0 to 1.2 times the height of a compound eye. Antennal foramina separated from each other by 0.5 to 0.8 times the distance between the foramen and the compound eye.

**Mesosoma** – Female. Anterior pronotal plate rounded dorsally or weakly incised (Fig. 3A) and with long white pubescence at the lateral areas and sparse pubescence on the central area, near the dorsal margin smooth or with a weak trace of transversely carinulate sculpture. Lateral surface of pronotum with quite dense pubescence and with coarse areolate sculpture. Mesoscutum in lateral view 1.5 to 1.6 times higher than long; in dorsal view 1.2 to 1.4 times wider than long. Median mesoscutal impression very short, at most a little longer than broad. Notauli reaching 1/2 to 2/3 the length of mesoscutum (Fig. 1A). There is a conspicuous line of
hairs on the anterior and lateral margins of the mesoscutum. Scutellum in dorsal view 1.40 to 1.47 times the length of the mesoscutum. Scutellar foveae smooth in the anterior part and with rugose sculpture in the posterior part (Fig 1A). Lateral pit of scutellar fovea big, 1.4 to 1.7 times longer than wide; the distance from median scutellar carina to the inner margin of the pit 2.8 to 3.2 times the width of the pit. Scutellar spine broad at base narrowing gradually towards apex (Fig 1A). Scutellar disc in lateral view slightly sloping to base of scutellar spine, which is horizontally directed at base and slightly curved downwards towards apex (Fig 3A). Mesopleural impression straight and wide (wider on the basal part) and without transverse carinae. Mesopleural triangle with dense pubescence anteriorly and sparse pubescence posteriorly.

Propodeum with coarse, areolate sculpture, lateral and median propodeal carinae absent. Male. Mesoscutum in lateral view 1.50 to 1.68 times higher than long; in dorsal view 1.06 to 1.20 times wider than long. The line of hairs on the anterior and lateral margins of the mesoscutum is weak. The scutellar foveae less sculptured than in the female. Scutellum in dorsal view 1.27 to 1.42 times the length of the mesoscutum. The distance from median scutellar carina to the inner margin of the pit 2.4 to 2.6 times the width of the pit. Scutellar spine almost straight in lateral view, the apex not ventrally directed. Mesoscutal impression not as wide as in the male.

Wings – Female. Marginal cell closed, 3.0 to 3.2 times longer than wide. Marginal pubescence of the wing starting from vein R1. Male. Marginal cell 2.9 to 3.0 times longer than wide.

Metasoma – Female. Petiole 3.00 to 3.25 times as long as wide, dorsally smooth, laterally smooth with short longitudinal carinae near the anterior end, ventrally longitudinally carinate. Third abdominal tergum dorsally 0.85 to 0.96 the length of the fourth tergum. Male. Petiole 2.66 to 3.00 times as long as wide. Third abdominal tergum dorsally 0.82 to 1.07 the length of the fourth tergum.

**Acanthaegilips masneri** Sporrong & Ros-Farré. sp. n.
(Figs. 1C, 3C)

**Etymology** – This name was chosen to honour Dr. Lubomir Masner, Canada, who has collected all the type specimens.

Length of head + mesosoma + metasoma: 2.9 mm to 3.1 mm.

**Colour** – Head, pronotum, mesopleuron, mesoscutum and scutellar spine black. Scutum, mesopleural triangle, metanotum and metasoma dark reddish brown. Procoxa and mesocoxa brown, trochanters and proximal margin of the tibiae light brown remaining part of the legs medium to dark brown. Mandibles light yellowish brown with reddish brown teeth. Scape dark brown with lighter apex, pedicel light reddish brown, F1 to first half of F2 brown, last half of the F2 to F8 light reddish brown, F9 to F11 dark brown. Veins of wing dark brown.

**Head** – Covered with scattered short hairs. Malar furrow slightly curved; postocular furrow absent (Fig 3C). Occipital carina weak. Pleurostomal lines very marked. Malar space 0.46 to 0.58 times the height of the compound eye. Transfacial line 0.48 to 0.53 times the greatest width of the head and 1.00 to 1.11 times the height of a compound eye. Antennal foramina separated from each other by 0.63 to 0.95 times the distance between the foramen and the compound eye.

**Mesosoma** – Anterior pronotal plate near the lateral margins with a few hairs; near the dorsal margin with weak irregular transverse carinae. Lateral pronotal carinae projecting dorsomedially to form a not very raised tooth (Fig 3C). Lateral surface of pronotum covered by sparse pubescence and with coarse areolate sculpture. Mesoscutum in lateral view 1.61 to 1.73 times higher than long; in dorsal view 1.36 times wider than long.
Median mesoscutal impression and notauli reaching 1/3 to 1/2 the length of mesoscutum. There is a conspicuous line of hairs on the anterior and lateral margins of the mesoscutum. Scutellum in dorsal view 1.26 to 1.37 times the length of the mesoscutum. Scutellar foveae smooth (Fig. 1C), scutellar spine dorsally smooth. Lateral pit of scutellar fovea rather small and almost circular 1.1 times longer than wide; the distance from median scutellar carina to the inner margin of the pit 3.7 times the width of the pit. Scutellar spine broad at base narrowing gradually towards apex (Fig. 1C). Scutellar disc in lateral view steeply slopping to base of scutellar spine, which is directed slightly upwards at base and curved downwards, so that the apex is pointing in a posteroventral direction. Mesopleural impression wide straight and without transverse carinae. Mesopleural triangle densely pubescent anteriorly, sparsely pubescent posteriorly. Propodeum with coarse areolate sculpture; lateral and median propodeal carinae absent.

**Wings** – Marginal cell closed 2.90 to 3.14 times longer than wide. Marginal pubescence starting from vein R1.

**Metasoma** – Petiole 2.25 to 2.33 times as long as wide. Petiole dorsally smooth; lateroventrally and ventrally longitudinally costate. Third abdominal tergum dorsally 0.56 to 0.70 times the length of the fourth tergum.

**Acanthaegilips occultus** Ros-Farré & Pujade-Villar sp. n.  
(Figs. 2C, 4C)

**Studied material** – 1 ♀; ♂ unknown. Holotype: 1 ♀ (MZLU-MS) 11/14-IV-1994 at Aragua, Parque Nacional H. Pittier, La Trilla (200 m), (Venezuela) L. Masner Col. (M.S).

**Etymology** – This name was chosen because the malar furrow of this species is very weak.

**Colour** – Head, mesosoma and metasoma black. Antennae light reddish brown, except the last four flagellomeres, which are dark brown. Mandibles light yellowish brown with reddish brown teeth. Front and middle legs light brown, hind legs brown. Veins of wing yellowish brown.

**Head** – Head without pubescence, except for a line of hairs running from base of mandible along gena behind malar and postocular furrows and a few hairs forming a perpendicular line just below eye along upper part of malar furrow. Malar furrow very weak and curved, only marked by a change in the integument curvature; postocular furrow weak. Occipital carina strong. Pleurostomal lines weak. Malar space 0.70 times the height of the compound eye. Transfacial line 0.50 times the greatest width of the head and 1.17 times the height of a compound eye. Antennal foramina separated from each other by 1.6 times the distance between the foramen and the compound eye.

**Mesosoma** – Lateral pronotal carinae projecting dorsomedially to form a much raised tooth (Fig. 2C). Anterior pronotal plate with a few scattered hairs near dorsolateral margins and weakly transversely carinate. Lateral surface of pronotum with dense pubescence and with areolate sculpture. Mesoscutum in lateral view 1.58 times higher than long; in dorsal view 1.20 times wider than long. Median mesoscutal impression reaching 1/4 part of the length of the mesoscutum. Notauli complete (Fig. 2C). Line of hairs on the anterior and lateral margins of the scutum absent. Scutellum in dorsal view of the same length as that of the mesoscutum. Scutellar foveae in anterior part with an internal short longitudinal carina dividing the anterior area of each fovea into two areas, scutellar foveae smooth with few irregular sculpture near its posterior margin. Lateral pit of scutellar fovea almost circular, 1.1 times longer than wide; the distance from median scutellar carina to the inner margin of the pit 3.5 times the width of the pit. Scutellar spine broad, narrowing abruptly before apex (Fig. 2C). Scutellar disc in lateral view steeply slopping to base of scutellar spine, which is upwards directed at base and curved downwards, the apex is ventrally directed. Mesopleural impression rather narrow, weakly curved in the apical part and with few coarse transverse carinae (Fig. 4C). Mesopleural triangle with sparse pubescence. Propodeum with areolate sculpture, lateral and median propodeal carinae present.

**Wings** – Marginal cell open 2.5 times longer than wide. R1 practically non-existent. Marginal pubescence of
the wing starting from the apical 2/3 of marginal cell but it is very sparse to the end of the cell.

**Metasoma** – Petiole between 1.0 and 1.5 times as long as wide, it is not possible to know exactly this measure because the third tergum is covering the posterior part of the petiole in the holotype. Petiole dorsally smooth, laterally and ventrally costate. Third abdominal tergum dorsally 0.65 times the length of the fourth tergum.

**Redescription of Acanthaegilips brasiliensis**
(Figs. 1D, 3D)

_Acanthaegilips brasiliensis_ Ashmead, (1897: 67)
_Acanthaegilips brasiliensis_ Ashmead, Dalla Torre & Kieffer, (1910: 47)
_Acanthaegilips brasiliensis_ Ashmead, Weld, (1921: 434)
_Acanthaegilips brasiliensis_ Ashmead, Weld, (1950: 96 & 171)
_Acanthaegilips brasiliensis_ Ashmead, Díaz, (1983: 46)

**Studied material** – 16♀ & 3♂. Holotype: 1♀ (nº 23645 USNM) Collected in April at Chapada (Brazil), Ashmead collection (det. Ashmead), antenna mounted. 
Label data: Chapada, April; Coll Ashmead. 

Length of head + mesosoma + metasoma in female: 2.6 mm to 3.2 mm; in male: 2.6 mm to 2.9 mm.

**Colour** – Female. Head wholly black. Antennae segments light brown with exception of the scape, which is black in its basal part, and F9 to F11, which are dark brown. Mandibles light brown with darker tooth. Scutum and mesopleural triangle reddish brown; mesopleuron, scutellar spine, propodeum and metasoma almost black. Legs medium to dark brown except for the procoxa, mesocoxa and tarsis, which are light brown. Gaster blackish brown. Veins of wings medium brown. Male. Entirely black with exception of the first and second legs, which are light yellowish brown.

**Head** – Female. Covered with scattered medium long hairs. Malar furrow slightly curved. Postocular furrow absent. Occipital carina present. Malar space 0.60 to 0.71 times the height of the compound eye. Pleurostomal lines strong. Transfacial line 0.52 to 0.57 times the greatest width of the head and 1.17 to 1.30 times the height of a compound eye. Antennal foramina separated from each other by 0.7 to 0.9 times the distance between the foramen and the compound eye. Male. Malar space 0.61 times the height of the compound eye. Transfacial line 0.54 times the greatest width of the head and 1.04 to 1.08 times the height of a compound eye. Antennal foramina separated from each other by the same distance as that between the foramen and the compound eye.

**Mesosoma** – Female. Lateral pronotal carinae projecting dorsomedially to form a raised tooth (Fig. 3D). Anterior pronotal plate with scattered long hairs on the lateral margins and with weak transverse cari-
nae. Lateral surface of pronotum with very sparse pubescence and with coarse areolate sculpture. Mesoscutum in lateral view 1.63 to 1.93 times higher than long; in dorsal view 1.20 to 1.53 wider than long. Median mesoscutal impression reaching between 1/3 and 1/2 the length of the scutum, notauli complete, the basal cell reaching to the 1/3 the length of mesoscutum (Fig. 1D). Sculpture over mesoscutum from the pronotum to the mesoscutal impression as a strong carina, when viewed in profile, mesoscutum humped, in part because of this carina, also seen in profile (Fig. 3D). There is a conspicuous line of hairs on the anterior and lateral margins of the mesoscutum. Scutellum in dorsal view 1.21 to 1.36 times the length of the mesoscutum. Scutellar foveae nude. Lateral pit of scutellar fovea 1.15 to 1.40 longer than wide; the distance from median scutellar carina to the inner margin of the pit 3.16 to 4.30 times the width of the pit. Scutellar spine broad at base and narrowing gradually towards apex (Fig. 1D). Scutellar disc in lateral view steeply sloping to base of scutellar spine, which is directed slightly upwards at base and curved downwards towards apex, which is ventrally directed. Mesopleural impression wide (wider on the basal part) straight and with weak transverse carinae or smooth. Mesopleural triangle densely pubescent anteriorly and very sparsely pubescent posteriorly (Fig. 3D). Propodeum with coarse areolate sculpture, median and lateral propodeal carinae absent. Male. Mesoscutum in lateral view 1.75 times higher than long; in dorsal view 1.25 to 1.32 wider than long. Basal cell of notauli shorter than in the female. Scutellum in dorsal view 1.42 times the length of the mesoscutum. Lateral pit of scutellar fovea 1.15 to 1.35 times longer than wide; the distance from median scutellar carina to the inner margin of the pit is 2.45 to 2.90 times the width of the pit. Scutellar spine less curved than in the female.

Wings – Female. Marginal cell open 3.00 to 3.18 times longer than wide. R1 practically reaching the margin of the wing like in the figure 5A. Marginal pubescence of the wing starting from vein R1. Male. Marginal cell 2.73 to 3.27 times longer than wide.

Metasoma – Female. Petiole 2.2 to 2.5 times as long as wide, dorsally smooth, laterally and ventrally costate. Third abdominal tergum dorsally 0.51 to 0.75 the length of the fourth tergum. Male. Petiole 2.7 times as long as wide. Third abdominal tergum 0.77 the length of the fourth tergum.

DISCUSSION

The Acanthaegilips genus presents two morphologically distinct groups. The first group is characterised by having the malar furrow slightly curved and by lacking the postocular furrow; the second group by having the malar furrow strongly curved in the upper part and the postocular furrow present. The first group includes A. macropennis, A. levis, A. masneri, A. brasiliensis, A. ashmeadi and A. diazi; the second group includes A. dantis, A. bugteri, A. occultus, A. alienus, A. exiguus and A. carinatus.

Members of the first group have the occipital carina weakly marked and the scutellar spine (dorsal view) narrowing gradually towards the apex, occasionally slightly constricted medially but never narrowing abruptly close to the apex. The marginal cell is open or closed; if it is open then R1 is always present. The propodeum is entirely areolate.

Members of the second group have a strongly marked occipital carina, with the exception of A. exiguus, which only has a faint carina. The scutellar spine is slender throughout or narrows abruptly close to the apex. The vein R1 is very short practically absent. The propodeum is areolate except in A. alienus, in which this sculpture is missing between the lateral propodeal carinae. Normally, longitudinal propodeal carinae are distinct despite the areolate sculpture [as opposed to the first group of species]. In A. occultus and A. carinatus the malar and postocular furrows are very weakly impressed but there is a line of hairs running slightly posterior to them.

In the species for which both sexes are known (A. macropennis, A. brasiliensis, A. ashmeadi, A. carinatus, A. bugteri), the males and females are very similar morphologically. Therefore, we are confident that we have correctly separated the two species known only by males from the four species known only by females.

Acanthaegilips alienus is very different from other members of the genus in the structure of the scutellar spine, the absence of modified flagellomeres in the males, the structure of the notauli and the absence of sculpture between the propodeal carinae. The last state differs from the likely ground-plan state of the Anacharitinae, in which the areolate sculpture covers the entire propodeum and more or less entirely obscures the propodeal carinae (Ros-Farré et al., 2000). The apomorphic state obviously evolved secondarily within the Anacharitinae through loss of the areolate sculpture making the propodeal carinae more conspicuous.
Two potentially important diagnostic characters for separating species of *Acanthaegilips* are the distribution of sensilla in the antennae and the position and number of modified flagellomeres. Unfortunately, we have not been able to explore the utility of these characters fully linked to sex – The first character varies between males and females and the second character occurs only in males – and both sexes are currently known for only half the species.

**ACKNOWLEDGEMENTS**

We are very grateful to Dr. C.R.F. Brandão and to the department’s colleagues N. Mercader, D. Bellido and S. Duran for helping us with the English translation and for the critics made on this manuscript. Also to Dr. C.R.F. Brandão (MZUSP), to Dr. J.D. Read (CNC), to Dr. D. Furth (USNM), to Dr. Godoy (UCR), to Dr. A. Penteado-Dias (DCBU), to Dr. C. Henrique (DCBU) and to Dr. A. Roig, Curador of Museo Argentino de Ciencias Naturales, for sending us part of the material cited in this work and to Dr. J.M. Maes (MEAN) for giving us some *Acanthaegilips* material.

EDITORIAL COMMITTEE

Editor-in-Chief: Hassam Zaher, Serviço de Vertebrados, Museu de Zoologia, Universidade de São Paulo, Caixa Postal 42.494, CEP 04218-970, São Paulo, SP, Brazil. E-mail: hzaher@iusp.br.

Associate Editors: Antonio C. Marques (Universidade de São Paulo, Brasil), Mario C.C. de Pona (Universidade de São Paulo, Brasil), Sergio A. Vanini (Universidade de São Paulo, Brasil).

INSTRUCTIONS TO AUTHORS
(MAY 2002)

General Information: Papéis Avulsos de Zoologia covers primarily the fields of Zoology, publishing original contributions in systematics, palaeontology, evolutionary biology, ecology, taxonomy, anatomy, behavior, functional morphology, molecular biology, oncology, faunistic studies, and biogeography. Papéis Avulsos de Zoologia also encourages submission of theoretical and empirical studies that explore principles and methods of systematics.

All contributions must follow the International Code of Zoological Nomenclature. Relevant specimens should be properly curated and deposited in a recognized public or private, non-profit institution. Tissue samples should be referred to their voucher specimens and all nucleotide sequence data (aligned as well as unaligned) should be submitted to GenBank (http://www.ncbi.nih.gov/Genbank/) or EMBL (http://www.ebi.ac.uk/).

Peer Review: All submissions to Papéis Avulsos de Zoologia are subject to review by at least two referees and the Editor-in-Chief. Three kplible copies (including photocopies of original illustrations) and original illustrations must be submitted; all authors will be notified of submission date. Authors may suggest potential reviewers. Communications regarding acceptance or rejection of manuscripts are made through correspondence with the first or corresponding author only. Once a manuscript is accepted providing changes suggested by the referees, the author is requested to return a revised version incorporating those changes (or a detailed explanation of why reviewer's suggestions were not followed) within four weeks upon receiving the communication by the editor. Revised manuscript must be submitted as both hard copy and electronic file (3.5” disk, Zip Drive, or CD Rom with text in Microsoft Word format). Figures and graphics should be sent separately (“.tiff”, “.xls”, “.cdr”).

Proofs: Page-proofs with the revised version will be sent to the first or corresponding author. Page-proofs must be returned to the editor within two weeks, preferably within 48 hours. Failure to return the proof promptly may be interpreted as approval with no changes and/or may delay publication. Only necessary corrections in proof will be permitted. Once page proof is sent to the author, further alterations and/or significant additions of text are permitted only at the author's expense or in the form of a brief appendix (“note added in proof”).

Submission of Manuscripts: Manuscripts should be sent to the Editor-in-Chief (H. Zaher, Museu de Zoologia da USP, Caixa Postal 42.494, CEP 04218-970, São Paulo, SP, Brasil). Manuscripts are considered on the understanding that they have not been published or will not appear elsewhere in substantially the same or abbreviated form. The criteria for acceptance of articles are quality and relevance of research, clarity of text, and compliance with the guidelines for manuscript preparation.

Manuscripts should be written preferentially in English, but texts in Portuguese or Spanish will also be considered. Studies with a broad coverage are encouraged to be submitted in English. All manuscripts should include an abstract in Portuguese and English regardless of the original language. Authors are requested to pay attention to the instructions concerning the preparation of the manuscripts. Close adherence to the guidelines will expedite processing of the manuscripts. Manuscripts deviating from the required form will be returned for revision prior to review.

Manuscript Form: Manuscripts should not exceed 100 pages of double-spaced typescript on 21 by 29.7 cm (A4 format) or 21.5 by 28 cm (letter format) paper, with wide margins. The pages of the manuscript should be numbered consecutively.

The text of articles should be arranged in the following order: Title Page, Abstracts, Body of Text, Literature Cited, Tables, Appendices, and Figure Captions. Each of these sections should begin on a new page. All typescript pages must be double-spaced.

(1) Title Page: This should include the title, author(s) name(s), institutions, and keywords in English as well as in the language of the manuscript, and a short running title in the language of the manuscript. The title should be concise and, where appropriate, should include mention of families and/or higher taxa. Names of new taxa should not be included in titles.

(2) Abstract: All papers should have an abstract in English and another in Portuguese, regardless of the original language. The abstract is of great importance as it may be reproduced elsewhere. It should be in a form intelligible if published alone and should summarize the main facts, ideas, and conclusions of the article. Telegraphic abstracts are strongly discouraged. Include all new taxonomic names for referencing purposes. Abbreviations should be avoided. It should not include references. Abstracts should not exceed 350 words.

(3) Body of Text: The main body of the text should include the following sections: Introduction, Materials and Methods, Results, Discussion, and Acknowledgments. Information of an introductory or summary nature should be placed in the abstract. For other details of manuscript preparation of format, consult the CBE: Style Manual, available from the Council of Science Editors (http://www.councilscienceeditors.org/publications/style.cfm).

Papéis Avulsos de Zoologia and Arquivos de Zoologia are publications of the Museu de Zoologia da Universidade de São Paulo (www.muz.usp.br).
